

Policy Memo | Why Limiting Climate Change Matters for Niger

Advice to the national delegation to the UNFCCC

To: Minister of Environment, Head of Niger's UNFCCC delegation	From: KOUAME Koffi Fidèle, Climate Adviser
Date: 14 October 2026	Subject: What Niger stands to lose, and to gain if warming is limited

Key message

Under current global policies, Niger would face about 91 days a year of dangerous heat by 2100, three times today's 31; if the world holds warming below 2 °C, that number stabilises at around 42. In an economy where farming and herding employ more than 80 % of people, mostly outdoors, this is the largest avoidable loss. Current policies would also make the heaviest multi-day rains about 43 % more intense, against 17 % below 2 °C. Severe drought months, however, will touch almost the whole country by 2030 in every scenario, so **Niger must both push for a rapid global phase-out of emissions and invest in adaptation now.**

1. Why Niger is unusually exposed, and not responsible

- **An open-air economy.** Agriculture and livestock account for almost 40 % of GDP and over 80 % of jobs, and depend overwhelmingly on rainfall (World Bank, 2024).
- **Shocks are already frequent and costly.** The 2005 and 2010 droughts triggered national food crises; the 2024 floods killed 339 people and affected more than 1.1 million (AFP, 2024).
- **A negligible contributor.** Niger emits a tiny share of global greenhouse gases: the losses below are driven by others' emissions, and can only be limited by others' cuts.

2. Three priority impacts: below 2 °C versus current policies

Source: Climate Impact Explorer (CIE), Niger, annual, area-weighted average. NGFS "Below 2 °C" (1.6 °C of global warming in 2100) versus "Current policies" (2.9 °C). Median of five climate models, 5–95 % range in brackets; the CIE flags results after 2060 as indicative.

Impact (CIE indicator)	Today (2020)	Below 2 °C	Current policies	Why it matters for Niger
1. Dangerous heat <i>Days per year with heat index above 40 °C</i>	31 days [25–38]	2050: 45 [33–69] 2100: 42 [29–72]	2050: 54 [41–84] 2100: 91 [59–134]	Above this threshold, sustained outdoor work risks heat exhaustion and heat stroke, and most Nigeriens farm, herd or build outdoors without cooling. CIE maps show a rise about twice as large in the populated south as in the north (+44 versus +21 days at 2 °C compared with 1 °C of global warming). WASCAL researchers project heat discomfort for over half of West Africa's population even at 1.5–2 °C (Sylla et al., 2018).
2. Severe drought <i>Share of land with at least one month of SPEI below –1.5 (%)</i>	84 % [72–97]	2050: 98 % [85–100] 2100: 98 % [81–100]	2050: ≈100 % [96–100] 2100: 100 % [98–100]	SPEI counts evaporation as well as rain, so it captures what heat does to soils, crops and pastures. By 2030, about 96 % of the country is affected in every scenario: severe drought months become the norm whatever the world does. Only a 1.5 °C pathway brings this back down (87 % by 2100). WASCAL crop modelling projects falling millet yields in most scenarios (Mohamed et al., 2025).
3. Extreme rainfall <i>Annual maximum 5-day precipitation, change from 1995–2014 (%)</i>	+8 % [–7 to +29]	2050: +18 % [0 to +55] 2100: +17 % [–1 to +54]	2050: +24 % [–1 to +67] 2100: +43 % [+5 to +110]	Heavier downpours on bare, crusted soils flood Niamey and the Niger River valley, where people, infrastructure and irrigated rice are concentrated. Under current policies, even the low end of the model range shows an increase by 2100. Extreme Sahelian storms have already tripled in frequency since 1982 (Taylor et al., 2017).

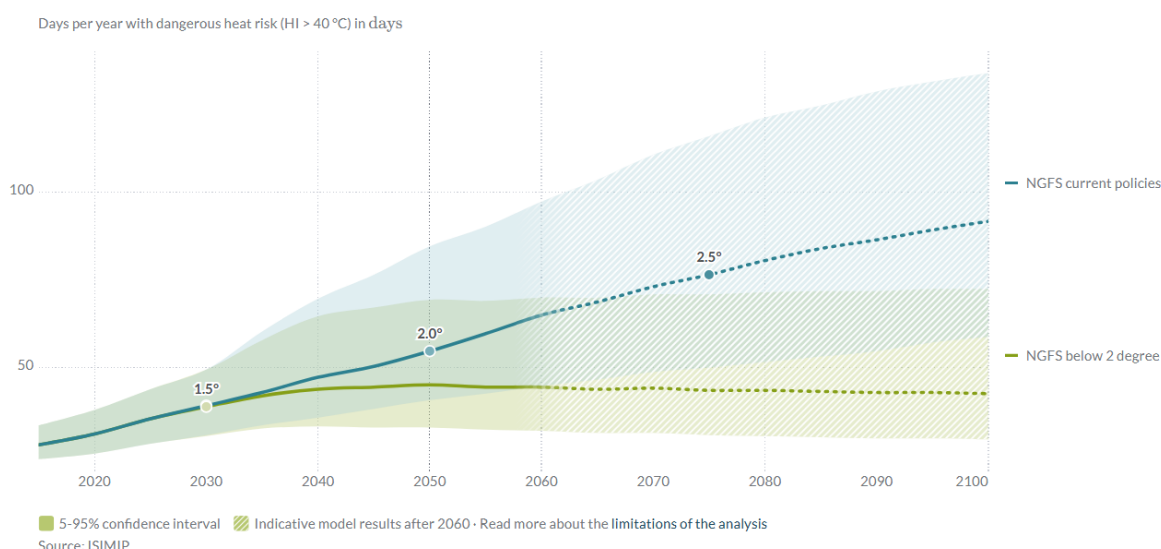

Figure 1. Days of dangerous heat per year in Niger: the gap between the two curves is what limiting warming saves. The two paths are identical until about 2030, then diverge: by 2100, current policies (blue) lead to about 91 days a year, against 42 below 2 °C (green) and 31 today. The shaded bands (model uncertainty) overlap, but even the low end of the current-policies range (59 days) exceeds the central below-2 °C estimate. Hatched area: results after 2060 are indicative. Source: Climate Impact Explorer, Climate Analytics (ISIMIP data).

3. Implications for Niger's national interest

Heat is the largest avoidable loss. Moving from current policies to a below-2 °C world avoids roughly 50 days of dangerous heat a year by 2100, nearly two months in which outdoor work, livestock and health are at risk. The World Bank (2022) estimates that climate change could cut Niger's annual GDP by 2.2 % (wet, optimistic scenario) to 11.9 % (dry, pessimistic scenario) by 2050, before counting migration or conflict.

Drought makes adaptation unavoidable in every scenario. Since severe drought months spread to almost the whole country by 2030 regardless of emissions, Niger cannot wait: drought-tolerant millet and sorghum, water harvesting, early warning and protection of herders' mobility are needed now. The risk is a cascade: hot, dry year → failed harvests and pastures → higher grain prices and distress sales of livestock → malnutrition, debt and farmer-herder tensions → emergency spending that crowds out investment.

Floods grow with every tenth of a degree. Extreme rainfall keeps intensifying under current policies (+43 % by 2100) but levels off below 2 °C (+17 %). Limiting warming directly reduces the flood risk facing Niamey and the river valley.

Recommended negotiating position

- (i) Defend the 1.5 °C goal: it is the only pathway that brings heat days back to today's level (32 by 2100) and reverses drought spread; press major emitters for NDCs consistent with a rapid fossil-fuel phase-out.
- (ii) Tie Niger's support to scaled-up, accessible adaptation finance for Least Developed Countries.
- (iii) Use the Loss and Damage Fund for droughts and floods, in coalition with the African Group and the LDC group.

4. What the evidence does, and does not, say

The direction of change is robust for heat; the size is not: by 2100 under current policies, models span 59 to 134 dangerous-heat days. Heat-index values rely on an approximation of humidity during the hottest hour, a limitation the tool itself notes. The drought indicator counts a single month of severe drought, so it saturates and barely separates scenarios. For extreme rainfall, the ranges include no change under low warming but not under current policies by 2100. The tool's only crop indicators (maize, rice, soy) were set aside because Niger's staples, millet and sorghum, are not modelled. Finally, these are hazard projections, not forecasts; Niger's high social vulnerability means real impacts are likely to be larger.
